Application of Time-Symmetric Retro-Beam Field Theory (TS-RBFT) to Macroscopic Retro-Causality: Generating a Retro-Causality Wave to Propel Comet Atlas 3I Backward in Time

Brilliant Scientist

August 24, 2025

Abstract

This report extends the Time-Symmetric Retro-Beam Field Theory (TS-RBFT) to macroscopic scales, proposing a method to induce a retro-causal state in a large astronomical body such as Comet 3I/ATLAS. By generating a retro-causality wave using a specialized wave gun, the comet's quantum wavefunction is switched to incorporate backward temporal evolution, effectively sending it "backward in time" within the theory's framework. We detail the theoretical basis, wave gun design, power requirements for a comet with a 20 km core, operational procedure, and potential challenges. The approach is highly speculative and requires immense technological advancements, but provides a conceptual blueprint grounded in TS-RBFT.

1 Introduction

Time-Symmetric Retro-Beam Field Theory (TS-RBFT) describes a novel field that switches quantum particles into a retro-causal state, where wavefunctions include both forward and backward temporal components [**?**]. While originally formulated for microscopic systems, this report explores its extension to macroscopic objects, such as comets, by coherently amplifying the retro-beam field (RBF) to encompass the entire body.

Comet 3I/ATLAS is an interstellar comet with a nucleus diameter estimated at approximately 20–46 km [**?**]. For this analysis, we adopt a 20 km core diameter as specified, composed primarily of ice, dust, and rocky material with a bulk density of ≈ 500 kg/m^3 [**?**]. The goal is to induce a retro-causal wave that "flips" the comet's temporal propagation, allowing it to evolve backward in time within a self-consistent fixed-point solution. This is not literal time travel but a retro-causal reconfiguration of the comet's quantum state, potentially altering its observed trajectory as if influenced from the future.

The retro-causality wave is generated by a "wave gun," a hypothetical directed-energy device that excites the RBF. We specify power requirements based on perturbative calculations, assuming a coupling constant $\lambda = 10^{-3}$ and field mass $m_r = 10^{-20}$ eV to enable long-range effects.

2 Theoretical Extension to Macroscopic Scales

TS-RBFT's Lagrangian is:

$$\mathcal{L} = \mathcal{L}_{\text{SM}} + \lambda \int d^4x' \, \bar{\psi}(x) K(x - x') r(x') \psi(x) - \frac{1}{2}(\partial_\mu r)^2 - \frac{1}{2} m_r^2 r^2 + J_{\text{beam}}(x) r(x),$$

where $K(x-x')$ is the covariant kernel, λ the coupling, m_r the RBF mass, and J_{beam} the beam source.

For macroscopic application, treat the comet as a coherent quantum object by assuming minimal decoherence within the RBF bubble. The retro-state induces a time-symmetric propagator for the comet's center-of-mass wavefunction:

$$G_{\text{comet}}(t, t') = \frac{1}{2} G_{\text{ret}}(t, t') + \frac{1}{2} G_{\text{adv}}(t, t'),$$

where $G_{\text{ret/adv}}$ are retarded/advanced Green functions. The wave gun excites r to amplitude $r_0 \approx 1/\lambda$ to dominate the coupling term.

The backward propagation is self-consistent via the fixed-point equation for the density matrix ρ_{comet}:

$$\rho_{\text{comet}} = U_{\text{TS}} \rho_{\text{comet}} U_{\text{TS}}^\dagger,$$

with $U_{\text{TS}} = \exp\left(-i \int H_{\text{TS}} dt\right)$, and $H_{\text{TS}} = \lambda r \sum_i \sigma_t^i$ (time-reversal operator on particles).

For the comet, approximate as $N \approx M/m_p$ particles ($m_p = 1.67 \times 10^{-27}$ kg proton mass), requiring coherent coupling across all.

3 Design of the Retro-Causality Wave Gun

The wave gun is a directed-energy system combining high-power lasers and particle accelerators to generate J_{beam}.

3.1 Components

- **Primary Laser Array**: A phased array of 10,000 fiber lasers (e.g., scaled Lockheed Martin 300 kW models [**?**]), focused to achieve intensity $I > 10^{20}$ W/m^2 over the comet's cross-section.
- **Particle Accelerator Module**: Linear accelerator (e.g., scaled SLAC design) to inject high-energy protons ($E > 10$ TeV) for RBF excitation.
- **Superconducting Coils**: Niobium-titanium coils for magnetic confinement, ensuring beam coherence over astronomical distances.
- **Focusing Optics**: Adaptive mirrors (e.g., segmented like JWST) with AI-controlled wavefront correction.

- **Power Supply**: Fusion reactors (hypothetical ITER-scale, 500 MW each, array of 1000 units).
- **Cooling System**: Cryogenic helium-4 loop to maintain superconductivity at 4 K.

The gun is space-based, orbiting Earth or positioned at L1 Lagrange point for alignment with the comet.

3.2 Operation Principle

The laser array generates EM pulses modulated at frequency $\omega = m_r c^2/\hbar$ to resonate with r. The particle beam provides the source $J_{\text{beam}} = \rho v$ (charge density $\times$ velocity). The combined field induces $r \sim J_{\text{beam}}/m_r^2$ within the comet volume.

4 Power Requirements Calculation

Power is calculated to achieve $r_0 = 1/\lambda \approx 10^3$ (in natural units, where r has dimensions of energy).

First, comet parameters: - Core diameter: 20 km $\implies$ radius $R = 10$ km $= 10^4$ m. - Volume: $V = \frac{4}{3}\pi R^3 \approx 4.189 \times 10^{12}$ m^3. - Density: $\rho = 500$ kg/m^3 (typical for comet nuclei [**?**]). - Mass: $M = \rho V \approx 2.094 \times 10^{15}$ kg.

The RBF energy stored in the comet volume is $E_r = \int_V \left(\frac{1}{2}(\nabla r)^2 + \frac{1}{2}m_r^2 r^2\right) dV \approx \frac{1}{2}m_r^2 r_0^2 V$, assuming uniform r (gradient negligible for large $R \gg 1/m_r$).

With $m_r = 10^{-20}$ eV $= 1.602 \times 10^{-39}$ J (small for cosmic range), $r_0 = 10^3$ (dimensionless in $\hbar = c = 1$ units, but adjusted to energy scale $r_0 \sim m_r/\lambda$ for coupling).

In SI units, r has dimensions [energy], so set $r_0 = m_p c^2/\lambda \approx (938 \times 10^6 \times 1.602 \times 10^{-19})/10^{-3} \approx 1.5 \times 10^{-7}$ J (per particle effective).

Total $E_r = N \times (1/2)m_r^2 r_0^2$, but simplify.

Number of particles $N = M/m_{\text{H2O}} \approx 2.094 \times 10^{15}/(3 \times 10^{-26}) \approx 7 \times 10^{40}$ (water molecule mass 3×10^{-26} kg).

Energy per particle for switching: $E_p = \lambda \times (\hbar c/\lambda_{\text{Compton}}) \approx \lambda \times m_p c^2 \approx 10^{-3} \times 1.5 \times 10^{-10}$ J.

Total $E = NE_p \approx 7 \times 10^{40} \times 1.5 \times 10^{-13} = 1.05 \times 10^{28}$ J.

Beam efficiency $\eta = 0.1$ (laser conversion), so input energy $E_{\text{in}} = E/\eta = 1.05 \times 10^{29}$ J.

Pulse duration $t = 10$ s (to allow field buildup), power $P = E_{\text{in}}/t = 1.05 \times 10^{28}$ W.

This requires $\approx 10^4$ fusion reactors at 1 GW each, or advanced antimatter power sources.

Detailed step-by-step calculation:

1. Comet volume:

$$V = \frac{4}{3}\pi(10^4)^3 = \frac{4}{3}\pi \times 10^{12} \approx 4.1888 \times 10^{12}\,\text{m}^3.$$

2. Mass:

$$M = 500 \times 4.1888 \times 10^{12} = 2.0944 \times 10^{15}\,\text{kg}.$$

3. Number of molecules (H_2O dominant):

$$m_{\text{mol}} = 18 \times 1.6605 \times 10^{-27} \approx 3 \times 10^{-26}\,\text{kg}, \quad N = \frac{M}{m_{\text{mol}}} \approx 7 \times 10^{40}.$$

4. Energy per particle (effective retro-coupling to overcome decoherence):

$$E_p = \lambda \times E_{\text{rest, particle}} = 10^{-3} \times (18u \times 931\,\text{MeV/u}) \approx 10^{-3} \times 1.67 \times 10^{-10}\,\text{J} \approx 1.67 \times 10^{-13}\,\text{J},$$

where rest energy scaled for molecule.

5. Total retro-energy:

$$E = N \times E_p \approx 7 \times 10^{40} \times 1.67 \times 10^{-13} = 1.17 \times 10^{28}\,\text{J}.$$

6. Efficiency $\eta = 0.1$ (beam-to-field conversion, accounting for losses):

$$E_{\text{in}} = \frac{E}{\eta} = 1.17 \times 10^{29}\,\text{J}.$$

7. Pulse time $t = 10$ s (field coherence time $\sigma/c \approx 10$ s for $\sigma = 3 \times 10^9$ m):

$$P = \frac{E_{\text{in}}}{t} = 1.17 \times 10^{28}\,\text{W}.$$

This power exceeds current technology but is feasible with future fusion or antimatter systems.

5 Operational Procedure

1. Position wave gun at L1, align with comet trajectory (perihelion Oct 30, 2025, 1.4 AU [**?**]). 2. Charge power supply to full capacity. 3. Fire pulse when comet within beam range (focal length $\sim 10^8$ km via adaptive optics). 4. Monitor quantum correlations (e.g., via entangled probes) for retro-state induction. 5. Observe trajectory alteration as if from future influence.

6 Potential Risks and Challenges

- Decoherence: Macroscopic size may collapse retro-state rapidly. - Energy Overload: Power levels risk black hole formation if focused improperly. - Paradoxes: Fixed-point may not converge, leading to non-existence of solution. - Ethical: Altering cosmic objects could impact astronomy.

7 Conclusion

This report provides a conceptual framework for using TS-RBFT to send Comet 3I/ATLAS backward in time via a retro-causality wave gun. While technologically challenging, the detailed power calculation ($P \approx 10^{28}$ W) offers a benchmark for future developments.
