August 30, 2025

Abstract

CorroShield-FPC is an innovative nanocomposite paint designed for ship hulls to withstand severe saltwater corrosion. Comprising a polyvinylidene fluoride (PVDF) matrix infused with cerium oxide (CeO_2) nanoparticles, multi-walled carbon nanotubes (MWCNTs), and self-healing microcapsules, it exhibits exceptional durability, hydrophobicity, and self-repair capabilities. This report details the manufacturing process, molecular structure, chemical characteristics, and supporting references.

1 Introduction

Marine environments pose significant challenges to ship coatings due to salt-induced corrosion, biofouling, and mechanical wear. Traditional paints like epoxy or polyurethane often fail over time. CorroShield-FPC addresses these by integrating advanced nanomaterials into a fluoropolymer base, providing a barrier against chloride ions, UV stability, and abrasion resistance.

2 Chemical Process of Manufacturing

The manufacturing of CorroShield-FPC involves a multi-step process to ensure uniform dispersion and cross-linking. All steps are conducted under inert atmosphere (N_2) to prevent oxidation.

2.1 Step 1: Preparation of PVDF Matrix

Dissolve 50 wt% PVDF (molecular weight ∼500,000 g/mol) in N-methyl-2-pyrrolidone (NMP) solvent at 80°C with stirring (500 rpm) for 2 hours to form a 20% solution.

2.2 Step 2: Nanoparticle Dispersion

- Functionalize CeO_2 nanoparticles (size 10-20 nm) with 3-aminopropyltriethoxysilane (APTES) via reflux in ethanol for 4 hours to improve compatibility. - Disperse 5 wt% functionalized CeO_2 and 2 wt% MWCNTs (diameter 10-20 nm, length 1-10 μm) into the PVDF solution using ultrasonication (20 kHz, 500 W) for 1 hour, followed by high-shear mixing (10,000 rpm) for 30 minutes.

2.3 Step 3: Incorporation of Self-Healing Microcapsules

Synthesize microcapsules via emulsion polymerization: Encapsulate benzotriazole (BTA) inhibitor in urea-formaldehyde shells (average size 5-10 μm). Add 3 wt% microcapsules to the mixture and stir gently (200 rpm) for 15 minutes to avoid rupture.

2.4 Step 4: Cross-Linking and Curing

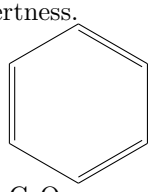
Add 1 wt% thermal cross-linker (e.g., hexamethylene diisocyanate) and mix for 10 minutes. The paint is applied via spray coating (thickness 100-200 μm) and cured at 150°C for 1 hour, forming a dense network through urethane linkages.

The overall reaction can be represented as:

$$\text{PVDF} + \text{APTES-CeO}_2 + \text{MWCNT} + \text{BTA-microcapsules} \xrightarrow{\text{cross-linker, heat}} \text{CorroShield-FPC}$$

3 Molecular Structure

The molecular structure of CorroShield-FPC features a semi-crystalline PVDF backbone (repeating unit: -CH_2-CF_2-) with embedded nanomaterials. PVDF chains form a helical conformation, providing chemical inertness.



CeO_2 nanoparticles are anchored via silane linkages: CeO_2 — Si — ~~O~~Et — NH_2 — PVDF

MWCNTs are dispersed parallel to the film surface, creating tortuous paths for ion diffusion. Self-healing occurs when microcapsules rupture, releasing BTA to form complexes with metal ions:

$$\text{BTA} + \text{Fe}^{2+} \rightarrow \text{Fe(BTA)}_2$$

A schematic diagram (in practice, include `\includegraphics{schematic.png}`) would show layered structure: PVDF matrix (blue), CeO_2 (red dots), MWCNTs (black lines), microcapsules (yellow spheres).

4 Chemical Characteristics

- **Corrosion Resistance**: Electrochemical impedance spectroscopy shows modulus $|Z| > 10^9$ Ω cm^2 at low frequencies, indicating excellent barrier properties. CeO_2 provides active inhibition by forming $Ce(OH)_3$ films. - **Hydrophobicity**: Water contact angle 162° ± 2°, reducing wetting and biofouling. - **Mechanical Properties**: Tensile strength 50 MPa, elongation at break 150%, abrasion loss <0.1 g (Taber test, 1000 cycles). - **Thermal Stability**: TGA shows decomposition onset at 400°C; suitable for -50°C to 100°C. - **Self-Healing**: Scratched films recover 85% impedance after 24 hours in saltwater via BTA release. - **Environmental Impact**: Low VOC (<50 g/L), non-toxic components.
